Vrije Universiteit, Amsterdam, The Netherlands

## Shortcomings of Existing Protection Schemes

System V IPC and POSIX Shared Memory lack flexibility and offer limited memory protection. Some shortcomings include:

- Coarse-grained, page-based protection
- Protection based on UID not process
- Access rights cannot be delegated
- No seamless integration for safe DMA

## Fine-grained, Delegatable Memory Grants

Process that wants to share memory creates a grant table, builds a memory grant, and sends index to other party: (proc ID, grant ID) identifies the grant.

Recipient of a memory grant must call the kernel in order to perform privileged grant operations. Kernel validates the access rights and performs the request.

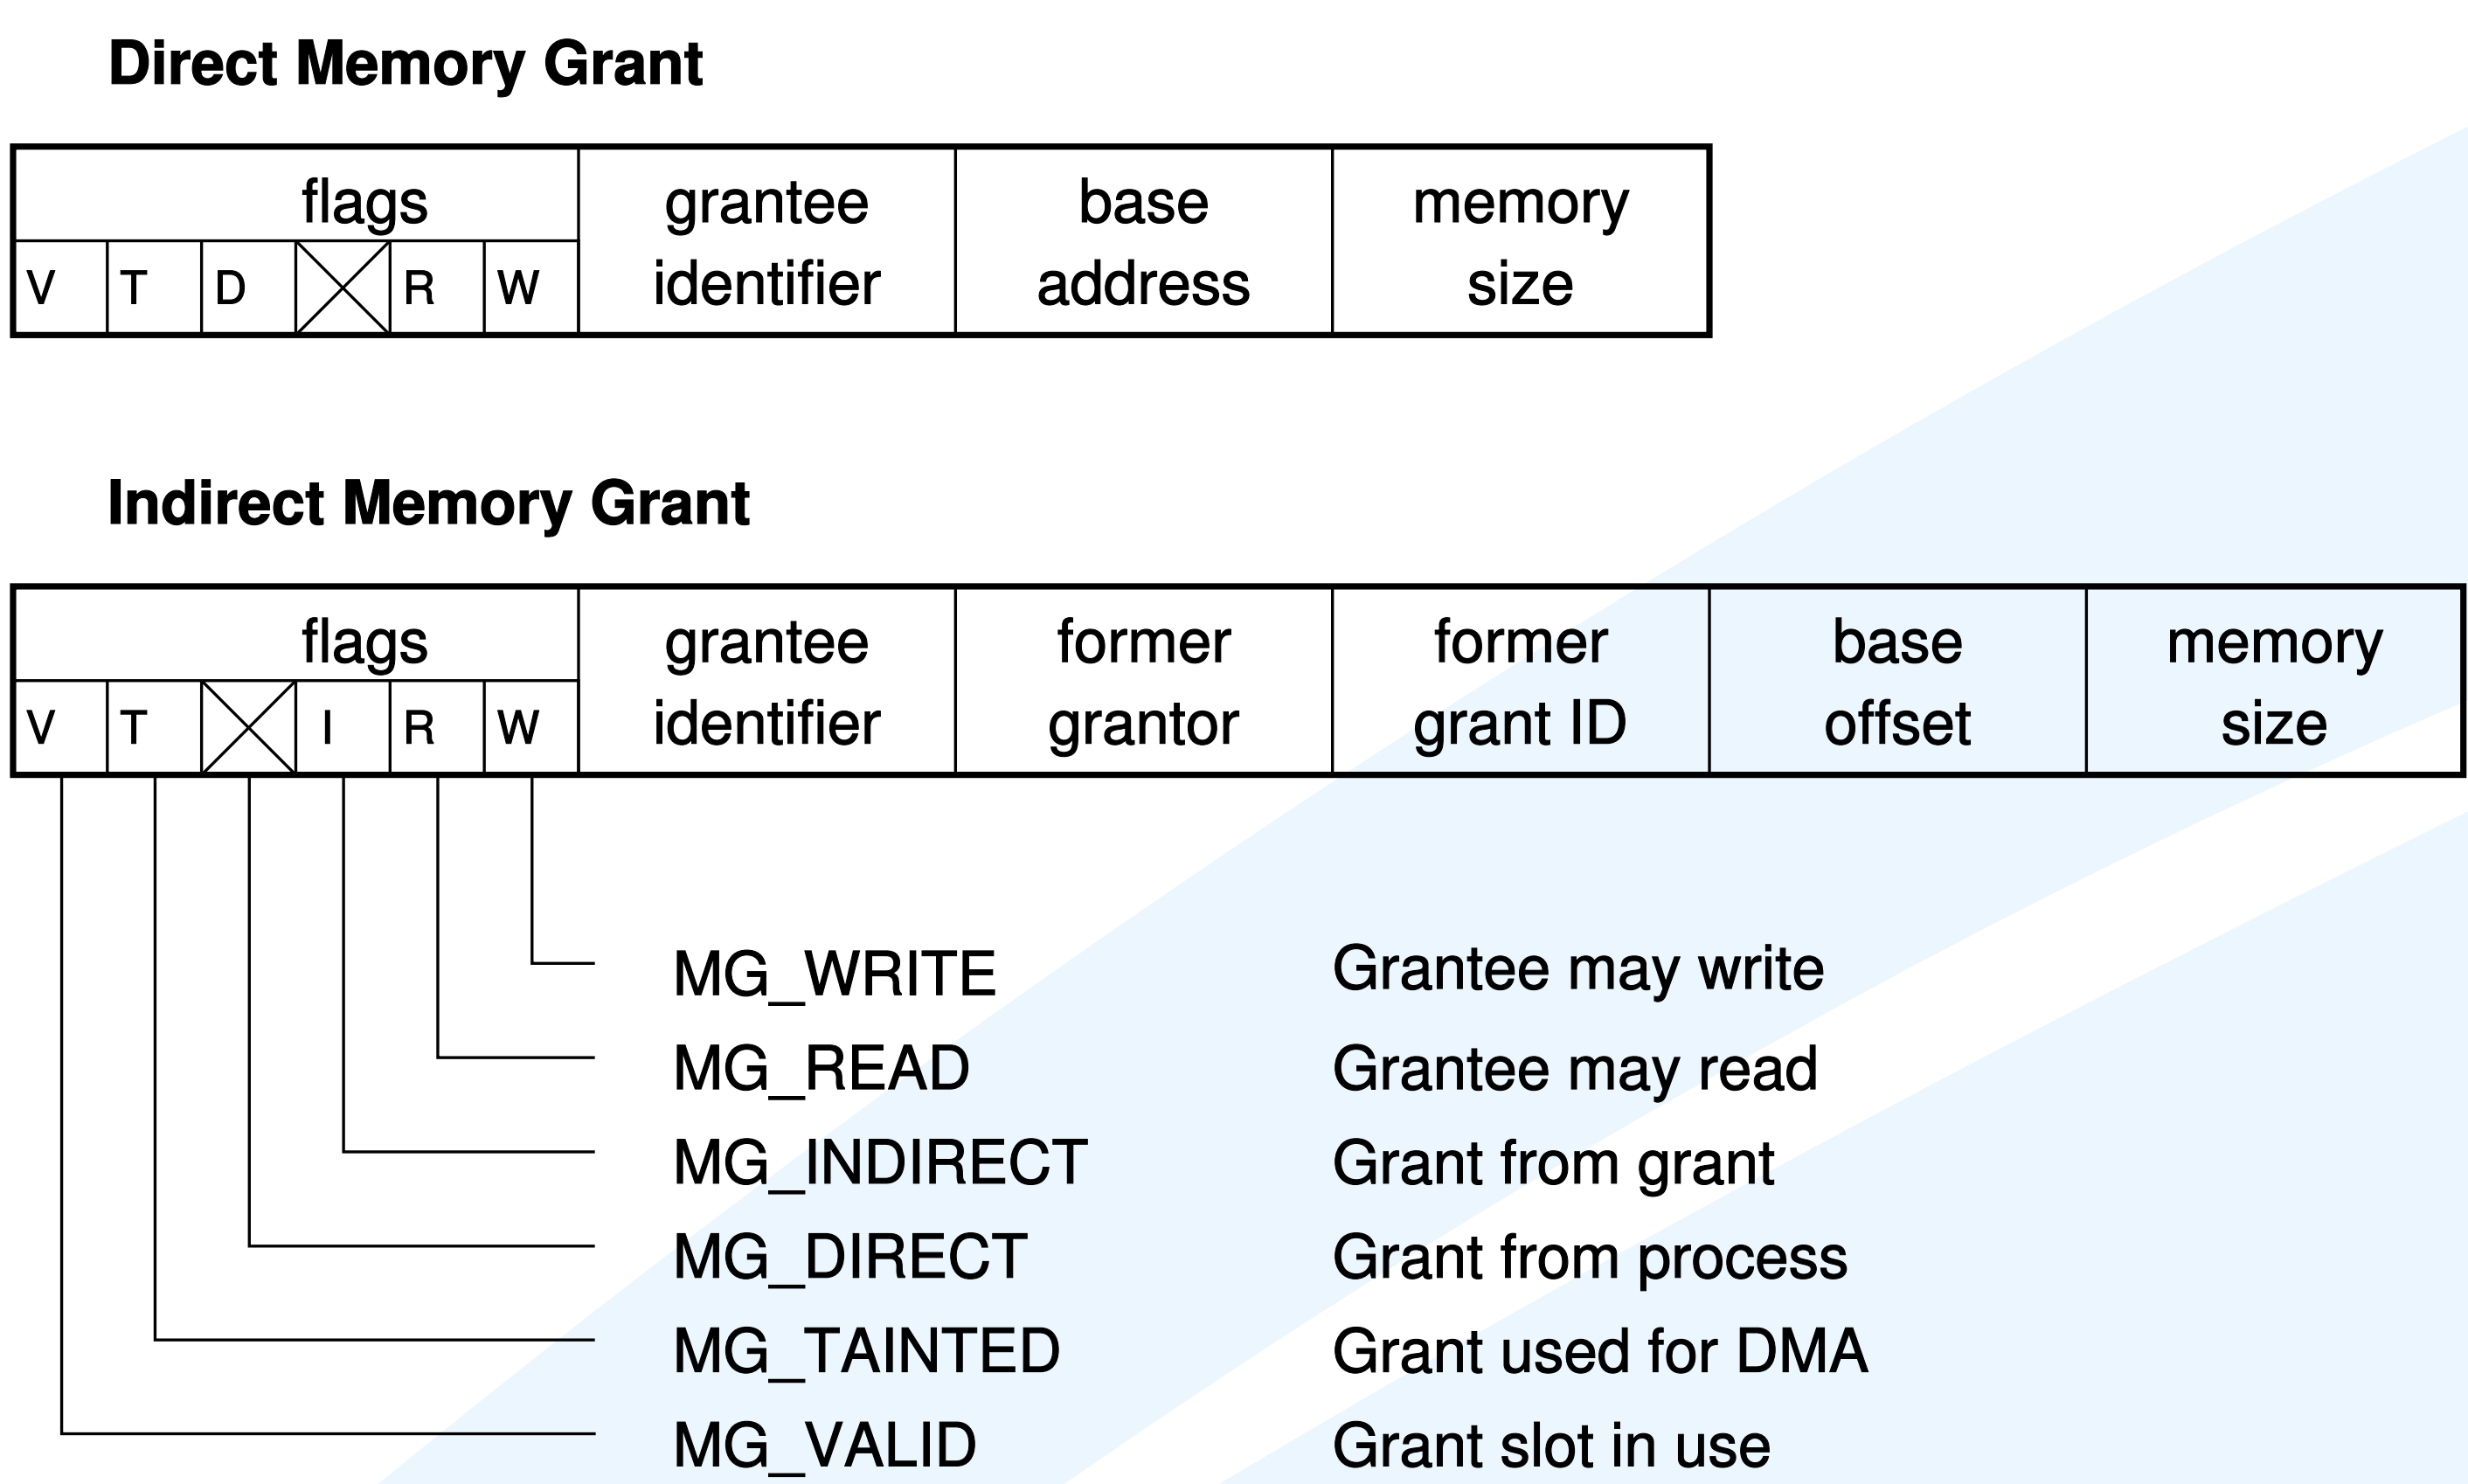

Definition of API and implementation of operations are a work in progress:

- Grant creation and revocation
- Memory copying
- Memory mapping
- Direct memory access (DMA)

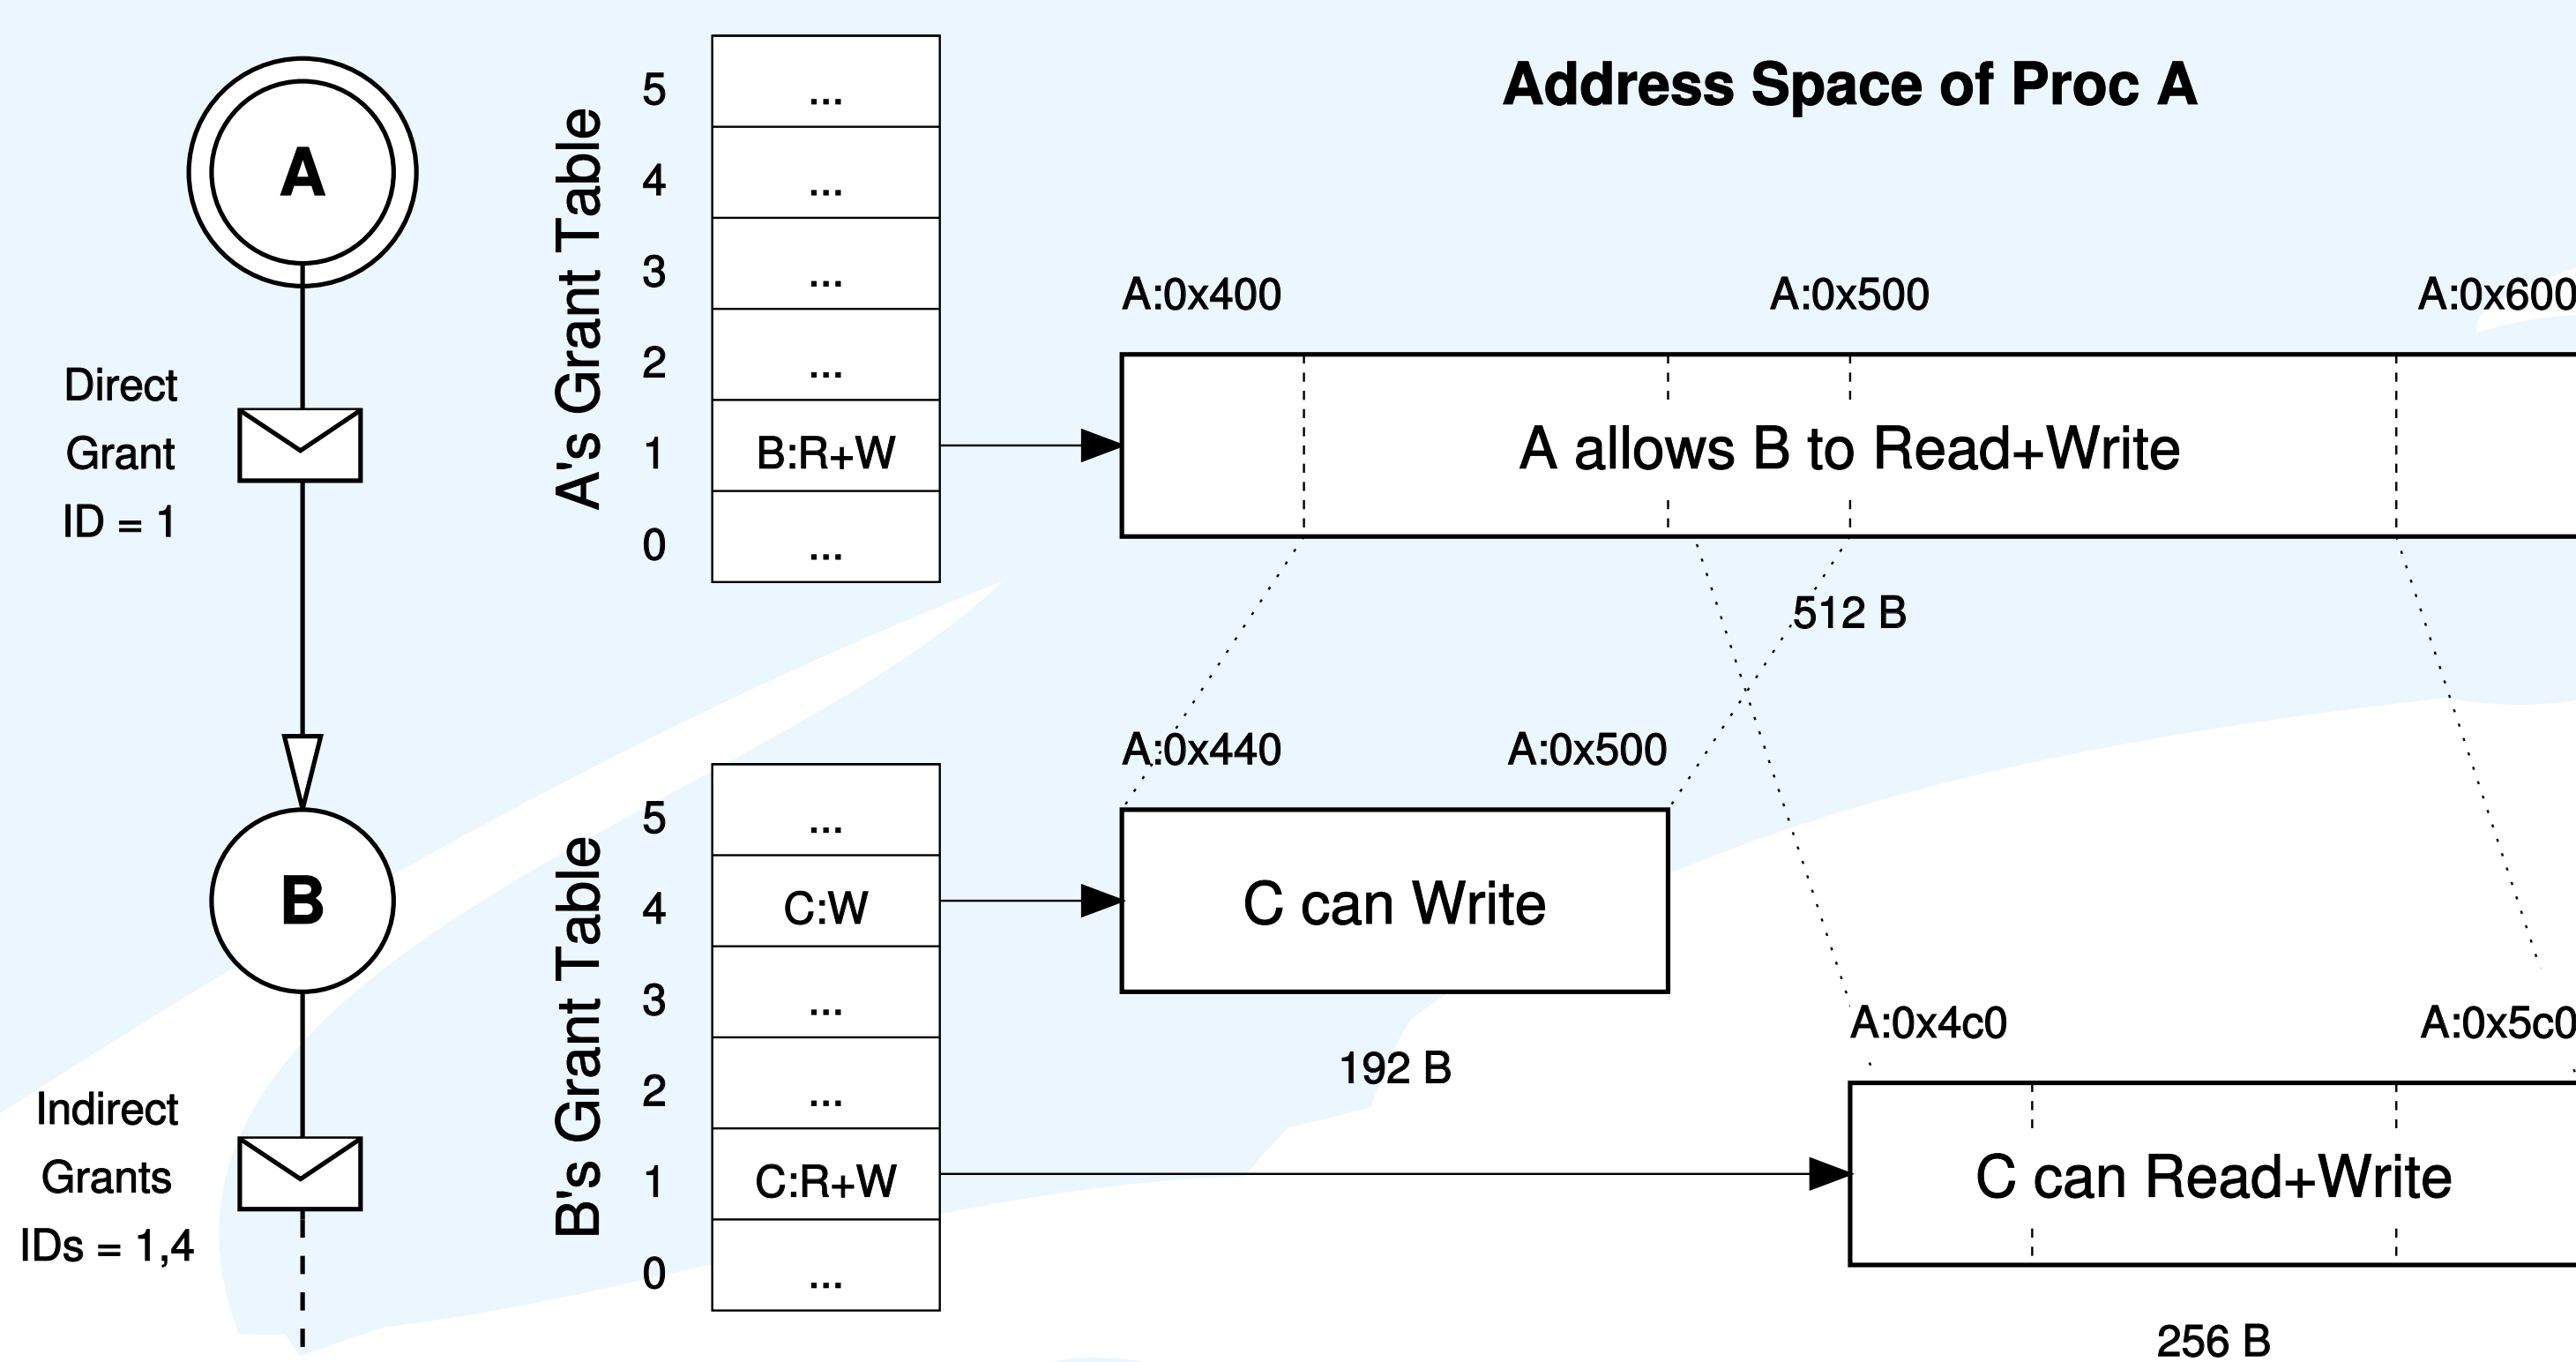

## Take-home Messages

- Memory grants are a novel alternative to existing memory protection models.
- Precise per-proces access control for byte-granularity memory regions.
- Used in MINIX 3 to protect against memory corruption by buggy drivers.

## Memory Grant Data Structure

## Grant Tables and Delegation

## Grants for Above Scenario

	flags	grantee	address	length
(A,1)	V <input checked="" type="checkbox"/> D <input checked="" type="checkbox"/> R W	B	0x400	0x200

	flags	grantee	granter	grant ID	offset	length
(B,1)	V <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> I R <input checked="" type="checkbox"/>	D	A	4	0x100	0x0C0
(B,4)	V <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> I R W	C	A	4	0x040	0x100
